

Fabric Semantic Model Agent — Workflow

How the agent is layered, how a consultant runs an engagement with it, and how it stays current with Microsoft

- Microsoft (vendored, read-only)
- Firm-owned (fsm-*)
- Client engagement
- Gate / approval

1 Knowledge layers & precedence

One entry skill; four layers; higher layer wins on conflict.

Rule of thumb

Microsoft's skill says HOW (tool routing, TMDL, MCP calls).
Firm skills say WHAT GOOD LOOKS LIKE (naming, structure, DAX style, gates).
Suppressing MS guidance is written in the firm skill — vendor/ is never edited.
Conflicts are logged to rules/precedence.md and reviewed on every upstream sync.

2 Upstream sync loop (keeping the Microsoft base current)

Weekly GitHub Action, or on demand via /sync-upstream. Nothing reaches a live engagement without a human merge.

What the evals are there to catch

Renamed MCP tools or changed invocation paths · new MS recommendations that contradict a firm rule · TMDL/PBIP fallback regressions.
CI can only exercise the TMDL / REST fallback paths — the Modeling MCP needs Power BI Desktop running locally. Keep evals honest about which path they test.

3 Engagement workflow (what a consultant actually runs)

Each phase must produce its artefact before the next starts. Gates are enforced by hooks, not just prose.

Tools the agent drives

Hooks (enforcement, not suggestions)

- block any write under vendor/ · lint TMDL + run BPA after every .tmdl edit
- block reading client DATA (not metadata) unless engagement.yaml allows
- block deploy to prod-tagged workspace without confirmation token
- no credentials / workspace IDs beyond engagement.yaml in the shared repo
